The 9-Barbaralyl Cation

Roald Hoffmann, W.-D. Stohrer, and M. J. Goldstein Department of Chemistry, Cornell University, Ithaca, N.Y., U.S.A. (Received August 12, 1971)

We find that the 9-barbaralyl cation assumes a structure with 3-fold symmetry in which there is an interesting orbital pattern caused by strong conjugative interaction of the central p orbitals with the cyclopropane rings. We think this symmetrical cation is identical with the transition state for the Cope rearrangement of 9-barbaralyl cation.

At -135°C, in super acid media, the 9-barbaralyl cation 1 undergoes a sequence of rapid rearrangements which renders all protons equivalent on the NMR time scale.¹⁾ Under solvolytic conditions evidence for a somewhat faster and less degenerate rearrangement

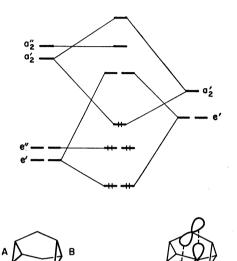

has been obtained.²⁾ In this process positions 3,7,9 are made equivalent, as are 1,2,4,5,6, and 8.

Several mechanisms may be written for both the partially degenerate and totally degenerate rearrangements. For the former process an attractive transition state or intermediate which in its molecular symmetry reflects the degeneracy of the rearrangement is the D_{3h} $C_9H_9^+$ cation 2 suggested by Schleyer and coworkers. Laborates a confluence of four areas of our interest: the ability of a cyclopropyl group to enter into conjugation, the concept of through-bond coupling, the modification of the Cope rearrangement, the structure and rearrangements of $(XH)_n$ species. We present here an analysis of its electronic structure.

Consider the interaction of the Walsh orbitals^{4,8)} of cyclopropane rings A and B of 2 with the set of three p orbitals at C₃, C₇ and C₉. These latter three orbitals

also generate a Walsh set, with a doubly degenerate e' orbital below a nondegenerate a_2 , but the splitting between e' and a_2 must be much smaller than in a normal cyclopropane because the C_3 – C_7 distance is long. Figure 1 shows the interaction of the orbitals of rings A and B with this inner set. The following points emerge:

- 1) The highest occupied MO is a_2 '. Interaction of the inner set with the Walsh orbitals of rings A and B reverses the direct overlap determined ordering e' below a_2 '. This is because the overlap of a C_3 p orbital with the optimally aligned Walsh orbitals of rings A and B is greater than its overlap with C_7 or C_9 p orbitals. In an extended Hückel calculation on **2** with CCC angles of 120° at C_3 , C_7 , and C_9 the a_2 ' orbital emerges 2.0 eV below e'.
- 2) The shape of the a_2 orbital is given in 3 below. Since it is composed of the a_2 combination of inner orbitals mixed in a bonding way with the antibonding a_2 combination of outer ring orbitals it leads to stronger C_1-C_9 , weaker C_1-C_2 bonds (only one member of the symmetry related set is given). a_2 is 3-7, 3-9, 7-9 antibonding, and so representation 2, if it implies any such bonding, is inappropriate.⁹⁾

⁹⁾ Similar results have been obtained by S. Yoneda, S. Winstein, and Z. Yoshida, This Bulletin, **45**, 2510 (1972). We are grateful to Dr. Yoneda for communicating his results to us prior to publication.

3) The collapse of **2** to **4** is a symmetry forbidden process. This is perhaps easiest seen by noting that the new 3-7 σ bond in **4** is symmetric with respect

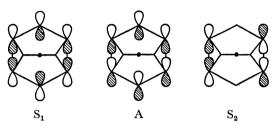

to reflection in the symmetry plane perpendicular to that bond, but the occupied a_2 orbital of 2 is antisymmetric. Thus the hypothetical rearrangement of 4 to 4 where the cationic center shifts from say C_7 to C_3 cannot proceed via the transition state or intermediate 2. A less symmetrical circumvention, like that we have discovered in $C_5H_5^{+},^{7e}$ is here made geometrically unlikely.

We now turn to the relationship of cation 2, its electronic structure described in Fig. 1, to the transition state 5 for the degenerate Cope rearrangement of $1\rightleftharpoons 1'$. This rearrangement was considered but dis-

carded as a source of degeneracy in the rearrangements of the 9-barbaralyl and 9-methyl-9-barbaralyl cations by Ahlberg, Grutzner, Harris, and Winstein. The basis for discounting the occurrence of a Cope

rearrangement was apparently the trend in Cope rearrangement activation energies on going from barbaralone to protonated barbaralone.¹⁰⁾ However we would like to reconsider the transition state **5** in view of its geometrical similarity to cation **2**.

The interconversion of **2** and **5** is a symmetry allowed process. Let us classify levels with respect to the mirror plane containing carbons 1, 9, and 5. The occupied levels in transition state **5** (or collapsed cation **1**) are two symmetric levels and one antisymmetric, shown schematically below.⁶) (The view is along the

 C_2 axis, from the top toward C_9). These correlate directly to the occupied levels of $\mathbf{2}$: S_1 and S_2 go to form the 2–8 and 4–6 σ bonds, while A by mixing with the empty p orbital at C_9 goes over into the crucial a_2 orbital of $\mathbf{2}$.

Given the structural similarities of $\mathbf{2}$ and $\mathbf{5}$ and the fact that they have similar electronic configurations we think it is highly likely that they are not distinct molecules but one and the same species. Whether this is a transition state or intermediate can be only decided by calculations better than the ones at our command. But we propose that the rearrangement of the 9-barbaralyl cation merges with the Cope rearrangement of the same molecule—the midpoint of that reaction is of D_{3h} symmetry and simply has three possible collapse channels.

We are grateful to P. v. R. Schleyer for a discussion this problem and R. Platt for assistance with some calculations. The stay of W. -D. S. at Cornell was made possible by a grant from the Deutsche Forschungsgemeinschaft. Our work was supported by the National Science Foundation and the National Institutes of Health.
